APPLICATION BUILDING USING ZIA ASSISTANT

1. Aim

To build a simple business application in Zoho Creator with the help of the Zia Assistant, using natural-language instructions to create application components such as forms, fields, reports, workflows, and other required elements.

2. Introduction

2.1 Zia Assistant

Zia is Zoho's AI-powered assistant that helps users work with Zoho applications using natural-language interaction. In Zoho Creator, an application requirement can be described in simple terms and Zia can assist with creating or configuring application components, reducing the amount of manual setup required.

2.2 Application Building with Zia

Application building using Zia combines the low-code capabilities of Zoho Creator with AI assistance. Instead of configuring every component manually, the user can describe the required application, data fields, and workflow. The generated components can then be reviewed, modified, tested, and used as part of the final application.

3. Objectives

- To understand the role of Zia Assistant in Zoho Creator application development.
- To create an application using natural-language instructions.
- To generate and configure forms and application components with AI assistance.
- To observe how Zia can reduce manual development effort in a low-code environment.
- To test and refine the generated application before deployment.

4. Requirements

- Zoho Creator account with access to application development features.
- A clear description of the application to be built.
- Required fields, data structure, and workflow requirements.
- Web browser and internet connectivity.

5. Procedure

Step 1 – Open Zoho Creator — Log in to Zoho Creator and open the application development area. Choose the option for creating a new application or working with an existing application.

Step 2 – Invoke Zia Assistant — Open Zia Assistant from the available AI-assisted application-building option and provide a natural-language description of the required application.

Step 3 – Describe the Application — Enter a clear requirement such as: “Create an Employee Leave Management application with employee name, employee ID, department, leave type, start date, end date, reason, and approval status.”

Step 4 – Generate Components — Allow Zia to interpret the requirement and generate the relevant application components such as forms, fields, views, or workflows.

Step 5 – Review the Generated Application — Check the generated field names, data types, form layout, validation rules, and workflow logic. Modify any component that does not match the requirement.

Step 6 – Test the Application — Enter sample records and verify that forms, reports, notifications, and workflows behave as expected.

Step 7 – Deploy or Use the Application — After successful testing, save the application and make it available to the intended users according to the application's access settings.

6. Sample Application – Employee Leave Management

A simple Employee Leave Management application can be created as an illustrative example. The application stores leave requests and can support an approval workflow.

Field	Purpose	Example
Employee Name	Stores the employee's name	Arun Kumar
Employee ID	Identifies the employee	EMP102
Department	Stores department information	CSE
Leave Type	Identifies the type of leave	Casual Leave
Start Date	Beginning of leave	21-09-2026
End Date	End of leave	22-09-2026
Reason	Reason for requesting leave	Personal work
Approval Status	Tracks the request status	Pending

7. Zia-Assisted Application Building Flow

1. Requirement	2. Natural-Language Prompt	3. Zia Processing	4. Component Generation	5. Review & Test	6. Final Application
Need identified	Describe app	AI interprets request	Forms / fields / workflow	Validate & modify	Use / deploy

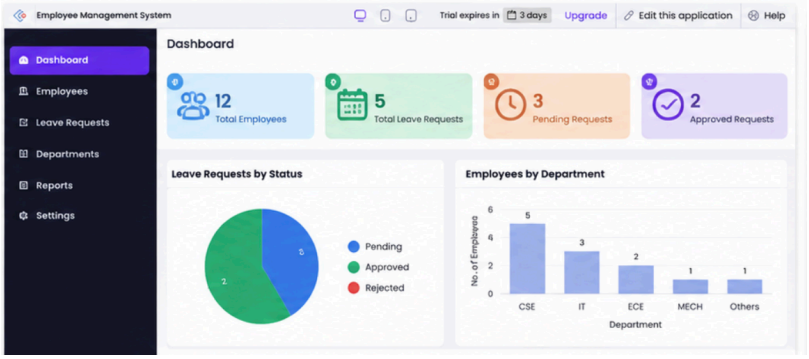

8. Advantages of Using Zia Assistant

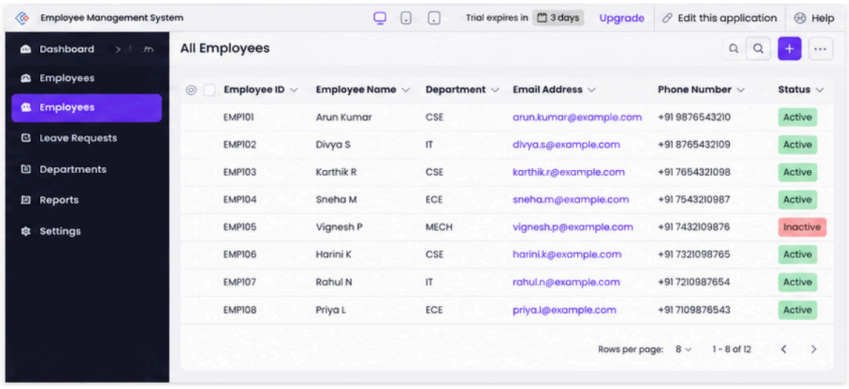

• Allows application requirements to be expressed in natural language.
• Reduces repetitive manual configuration of common application components.
• Can accelerate the initial creation of forms, fields, and workflows.
• Helps beginners work with low-code application development more easily.
• Generated components can be reviewed and edited by the developer.

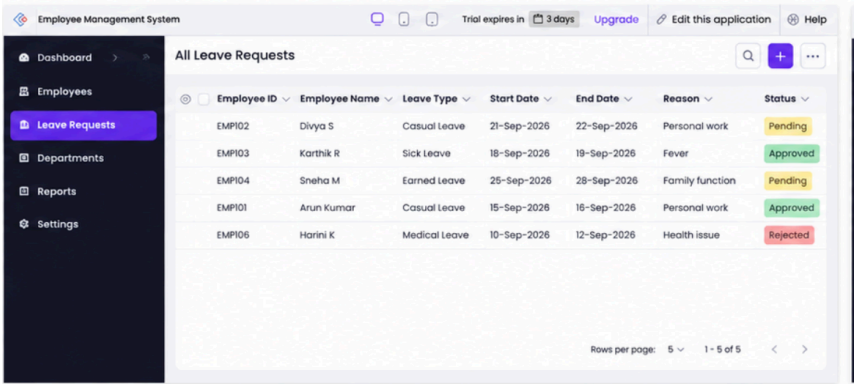

9. Limitations / Considerations

• The generated application should be reviewed for correctness before use.
• Complex or highly specialized requirements may still require manual configuration or scripting.
• The quality of the result depends on how clearly the requirement is described.
• Testing and validation remain necessary after AI-assisted generation.

10. Screenshot

10. Result

The application-building activity was successfully performed using Zia Assistant. Natural-language requirements were used to guide the creation of application components, followed by review and testing. The exercise demonstrates how AI assistance can be combined with Zoho Creator's low-code environment to speed up application development.

11. Conclusion

Application building using Zia Assistant provides an AI-assisted approach to low-code development. By describing requirements in natural language, users can reduce manual configuration and quickly create the initial structure of a business application. Human review, customization, and testing remain important to ensure that the final application meets the required functional and data requirements.
